Abstract

Oocytes from prepubertal animals have a reduced ability to undergo embryo development and produce viable offspring. The present work used an ovine model consisting of oocytes derived from adult and prepubertal donors to assess the molecular status of oocytes and preimplantation embryos with different developmental competence. The lower potential of oocytes of young donors was confirmed in terms of *in vitro* developmental capabilities and kinetics. A panel of genes including maternal effect (*DPPA3, GDF9, NMP2, ZAR1)* and housekeeping genes (*ACTB, RPL19, SDHA, YWHAZ, ATP1A1)*, genes involved in DNA methylation *(DNMT1, DNMT3A, DNMT3B),* genomic imprinting *(IGF2R)*, pluripotency (*NANOG, POU5F1)* and cell cycle regulation *(CCNB1, CDK1, MELK*) was relatively quantified. Temporal analysis during oocyte maturation and preimplantation embryo development evidenced patterns associated with donor age. With a few gene-specific exceptions, the differential model showed a reduced transcript abundance in immature prepubertal oocytes that completely reversed trend after fertilization, when higher mRNA levels were consistently observed in early embryos, indicating a delay in maternal transcript degradation. We propose that the molecular shortage in the prepubertal oocyte may affect its developmental potential and impair the early pathways of maternal mRNA clearance in the embryo.

While confirming the different potential of oocytes derived from adult and prepubertal donors, our work showed for the first time a consistent delay in maternal transcript degradation in embryos derived from low competence oocytes that interestingly recalls the delayed developmental kinetics. Such abnormal transcript persistence may hinder further development and represents a novel perspective on the complexity of developmental competence.

69 **Introduction**

70 The use of gametes derived from prepubertal animals in *in vitro* embryo production systems was initially
71 triggered by the interest in improving livestock breeding programs, in terms of reduction of the generational
72 interval and increase in reproductive efficiency (Khatir et al, 1996; Nicholas 1996; Morton 2008*)*. Gametes
73 from prepubertal oocytes were indeed seen to be competent to undergo normal embryo development and
74 produce viable offspring, albeit with lower rates (Armstrong et al, 1992; Revel et al, 1995; Armstrong et al,
75 1997; Ledda et al, 1999). The efforts in identifying the reasons for the reduced developmental competence not
76 only improved the rates of embryo production from prepubertal donors (Earl et al, 1995; Ledda et al, 1999),
77 but interestingly shed light into numerous aspects involved in oocyte potential. Morphological, cellular,
78 biochemical and molecular studies confirmed the differential competence of gametes derived from adult and
79 prepubertal donors in terms of resistance to cryopreservation (Leoni et al. 2006), metabolism and ultrastructure
80 (O'Brien et al, 1996), transcript abundance (Leoni et al. 2007, Romar et al. 2011, Ledda et al. 2012, Bebbere et
81 al, 2014), *in vitro* developmental competence and kinetics (Majerus et al, 1999; Leoni et al. 2006, 2015;
82 Landry et al, 2016), mitochondrial distribution (Leoni et al. 2015) and methylation dynamics (Masala et al,
83 2017). Although the differential model has become a useful research tool independently on its breeding
84 application, the limited competence of prepubertal oocytes is yet not fully understood.

85 The reduced developmental ability of prepubertal gametes is most likely due to several interdependent factors,
86 which reflect the incomplete sexual maturity and related hormonal state of the animal. Oocytes retrieved from
87 adult donors originate from the cyclic recruitment of ovarian follicles, when dynamics are under the control of
88 a full hypothalamus-hypophysis-ovary axis. Conversely, oocytes collected from prepubertal donors derive
89 from the initial recruitment (reviewed in McGee and Hsueh 2000), when the primordial follicles that leave
90 their resting state and start to grow, develop to early antral stage, but physiologically proceed to atresia. That's
91 because the levels of gonadrotrophins to which follicles are exposed in the prepubertal female are insufficient
92 to promote further follicular growth. In accordance, ovarian stimulation using FSH of prepubertal donors was
93 seen to improve the rate of blastocyst formation, underlining the importance of hormonal environment to
94 insure oocyte ability to sustain development (Khatir et al, 1996).

95 In metazoans, oocyte maturation, fertilization and early embryo development happen in the absence of *de novo*
96 transcription; as a consequence, these events rely on the molecules that are stored during oocyte growth. Such

For Peer Review

1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 32 33 34 35 36 37 38 39 40 41 42 43 44 45 46 47 48 49 50 51 52 53 54 55 56 57 58 59 60

97 maternal control lasts until activation of the nascent embryonic genome (EGA); by this time, the mRNAs of
98 maternal origin are degraded and replaced by the molecules synthesized by the embryo. The molecular
99 baggage of the oocyte is therefore crucial for the first developmental phases of the embryo and affects the
100 activation of its genome as well. The accumulation of transcripts during oocyte growth occurs during follicle
101 recruitment, it is thus likely affected by the different hormonal status encountered during initial or cyclic
102 recruitment. In accordance, abundant literature sustains the cytoplasmic immaturity of prepubertal oocytes in
103 terms of abundance of specific transcripts (Oropeza et al, 2004, Leoni et al, 2007; Bebbere et al, 2014; Bernal-
104 Ulloa et al, 2016; Masala et al, 2017).
105 Aim of the present work was to assess the effect of oocyte donor age (adult or prepubertal) on the molecular
106 status of oocytes and preimplantation embryos. An ovine model consisting of non-hormonally treated adult
107 and prepubertal donors was used to analyze the temporal expression of a panel of seventeen genes involved in
108 different cell functions. In parallel, oocyte differential quality was assessed in terms of *in vitro* developmental
109 capabilities and kinetics.
110

111
Results

112 ***In vitro* development of adult and prepubertal oocytes.**

113 ***In Vitro* Embryo Production**

114 A total of 740 oocytes derived from prepubertal donors and 671 from adult ewes were employed to evaluate *in*
115 *vitro* developmental competence. Maturation rate is similar in oocytes obtained from adult or prepubertal
116 animals (Table 1). After fertilization, a significantly lower number of embryos cleaved ($P<0.01$) in the
117 prepubertal group compared to the adult one with 60.4% prepubertal and 69.9% adult cleaved oocytes (Table
118 1). In addition, the kinetics of the first cleavage showed significant differences between the two groups, with a
119 general delay in the timing of division in the prepubertal gametes (Table 1). Most oocytes derived from adult
120 donors cleaved by 24 hrs post-fertilization, while the majority of prepubertal derived gametes required a
121 longer time. The lower developmental competence of prepubertal oocytes was confirmed by the poorer
122 development to blastocyst stage in terms of absolute rate (24.94% vs 59.73%, $P<0.01$) and developmental
123 kinetics [1.67 % vs 17.45%, $P<0.01$ at 6 days post fertilization (d) and 12.8% vs 29.9%, $P<0.01$ at 7d; Table
124 2].

6
7 127 The quantification of the exogenous *luciferase* mRNA performed by reverse transcription and Real Time PCR
8
9 128 showed an RNA recovery rate of 52 ± 5 % (Mean ± SE) and no differences among samples.
10
11 129
12
13 130 **Gene expression in oocytes and pre-implantation embryos deriving from adult and prepubertal donors**
14
15 131 To investigate the relative expression of a panel of genes during oocyte maturation and embryo
16
17 132 preimplantation development, oocytes and embryos were pooled in equal number (n=10 per pool). The
18
19 133 relative quantification of all transcripts was performed after normalization against the exogenous *luciferase*
20
21 134 mRNA levels and the equal number of oocytes and embryos (Su et al. 2007; Ohsugi et al. 2008; Evsikov and
22
23 135 Evsikova 2009).
24
25 136 Messenger RNAs of all evaluated genes were detected in GV and MII oocytes and in embryos up to the 16C
26
27 137 stage, independently of the donor age. In most cases, maximal transcript abundance was observed in the
28
29 138 immature oocyte and decreased during embryo preimplantation development, with gene-specific patterns (Fig.
30
31 139 1-5). Conversely, *NANOG* mRNA level highest level was observed in embryos at the 8- and 16- cell stage (Fig
32
33 140 4).
34
35 141 In adult-derived oocytes most genes (*ACTB*, *DPPA3*, *GDF9*, *MELK*, *NPM2*, *POU5F1/OCT4, SDHA*, *RPL19*,
36
37 142 *ZAR1* and *YWHAZ)* showed a significant reduction in mRNA abundance during oocyte maturation;
38
39 143 conversely, only *NPM2* transcript decreased in prepubertal gametes (Panel A of figures 1-5). All transcripts
40
41 144 showed a major drop around fertilization (mature oocytes vs two-cell embryos) in embryos derived from adult
42
43 145 and prepubertal donors, with the exception of *YWHAZ, NANOG* and *CCNB1* in prepubertal embryos.
44
45 146 *ACTB, RPL19, ATP1A1, DPPA3, NPM2, DNMT1* and *DNMT3B* mRNAs maintained a steady level in adult-
46
47 147 derived embryos of 2-, 4-, 8- and 16-cells, while *CCNB1, SDHA, GDF9, IGF2R, MELK, YWHAZ and ZAR1*
48
49 148 abundance was unvaried in 2-, 4- and 8- cell embryos, and significantly decreased in 16-cell stage embryos.
50
51 149 *DNMT3A* transcript showed a significant drop in abundance in embryos at the 4C stage.
52
53 150 Conversely, embryos derived from prepubertal donors showed more variable patterns, with significant drops
54
55 151 between 2- and 4- cell stage (*ZAR1*, *CDK1*), most often between 4- and 8- (*MELK*, *ZAR1*, *SDHA*, *ATP1A1,*
56
57 152 *GDF9, CCNB1, CDK1, IGF2R, DNMT1* and *DNMT3B*), or 8- and 16- (*MELK*, *ZAR1*, *GDF9*, *CCNB1,*
58

1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 32 33 34 35 36 37 38 39 40 41 42 43 44 45 46 47 48 49 50 51 52 53 54 55 56 57 58 59 60

153 *CDK1*). In a few cases (*DPPA3*, *YWHAZ* and *RPL19),* the decrease during embryo development was so
154 gradual that a significant decline was observed only between non-consecutive stages of embryo development
155 (i.e. *DPPA3* in 2- vs 8- cell stages; Panel A of Figures 1-5).

156 Comparison between the expression patterns of adult vs prepubertal groups within each developmental stage
157 (ie. Adult GV vs Prepubertal GV; Adult MII vs Prepubertal MII and so on; Panel B of figures 1-5) showed
158 consistent differences which are summarized in Table 3. The analysis in oocytes revealed similar abundance
159 for most mRNAs, with the exception of *ACTB*, *DPPA3*, *MELK*, *NANOG, POU5F1, RPL19* and *ZAR1* that
160 show lower levels in GV prepubertal oocytes and *NPM2* transcript, which is more abundant in prepubertal MII
161 oocytes (Panel B of figures 1-5 and Table 3). Conversely, most mRNAs show significant differences in
162 embryos around the 2- and 4- cell stage [2 cell stage: *CDK1, DNMT3A, DPPA3, GDF9, IGF2R, MELK,*
163 *NPM2, SDHA, POU5F, ZAR1;* 4 cell stage: *CCNB1*, *CDK1, DNMT3A, GDF9, MELK, POU5F1, RPL19,*
164 *SDHA]*. No transcripts varied at the 8- or 16- cell stage. Overall, only four out of 17 genes (*DNMT1,*
165 *DNMT3B, YWHAZ* and *ATP1A1*) did not differ in oocytes or embryos from donors of different age; most
166 notably, all differentially expressed genes show lower abundance in oocytes, but higher levels in embryos
167 derived from prepubertal donors (Panel B of figures 1-5 and Table 3).

168 NANOG is the only analysed mRNA whose transcription is resumed by the nascent embryo genome at the 8-
169 and 16- cell stage (Figure 4A and B). Both in adults and in prepubertal oocytes, *NANOG* abundance is steady
170 during oocyte maturation. Conversely, it drops significantly around fertilization in adults, but not in
171 prepubertal embryos (Figure 4A). While a significant higher abundance is observed in adult GV oocytes
172 compared to prepubertal ones, no differences were observed between the two groups during further
173 developmental stages (Figure 4B).

174

175 **Gene expression in embryos at the blastocyst stage**

176 As expected, the expression of MEGs *(ZAR1, NMP2, DPPA3, GDF9)* was not detected at the blastocyst stage.
177 The other studied genes were expressed, but showed no difference in transcript abundance between adult or
178 prepubertal derived blastocysts.

2
3 181 # Discussion
4
5 182 The most relevant finding of the present work is the delay in maternal transcript degradation observed in
6
7 183 embryos derived from low competence oocytes before EGA. Such abnormally prolonged transcript persistence
8
9 184 was never reported in early embryos and is most probably involved in the lower developmental competence of
10
11 185 oocytes of derived from prepubertal donors.
12
13 186 The study was performed on a previously developed ovine model of differential developmental competence
14
15 187 consisting of ovine oocytes derived from non-hormonally treated adult and prepubertal donors. Similar models
16
17 188 were previously analyzed in terms of morphology, metabolism and molecular status (Leoni et al. 2006, 2007
18
19 189 and 2015; Romar et al. 2011; Ledda et al. 2012); in the present work, preliminarily to the molecular analysis,
20
21 190 we confirmed the reduced developmental potential of prepubertal gametes in terms of *in vitro* developmental
22
23 191 capabilities and kinetics. As expected, no differences were observed in terms of IVM, but both cleavage and
24
25 192 blastocyst absolute rates and kinetics differed between the two groups of oocytes (Table 1 and 2), with
26
27 193 prepubertal embryos achieving lower rates in a longer time. Such observations are in agreement with previous
28
29 194 results obtained in several species (Leoni et al, 2006; Landry et al, 2016) and confirmed the lower potential of
30
31 195 gametes derived from prepubertal donors.
32
33 196 The temporal expression analysis of the panel of genes showed specific patterns in oocytes and embryos
34
35 197 derived from adult and prepubertal donors (Figures 1A-5A). The late EGA that characterizes large domestic
36
37 198 animals compared to rodents (8-16 cell stage vs 1-2 cell stage) allowed to detail the expression patterns from
38
39 199 fertilization to EGA, identifying the variations specific to the different developmental stages.
40
41 200 With a few gene-specific exceptions, analysis during maturation and early development in the adults
42
43 201 evidenced some common features. First of all, relative quantification over oocyte maturation often showed a
44
45 202 consistent drop in transcript abundance. As expected, such decrease was observed for all MEGs, with a drop of
46
47 203 about 50% for *DPPA3*, *ZAR1* and *GDF9* and 89% for *NPM2* (Figure 2A). The same decrease was observed in
48
49 204 all but one housekeeping genes (Figure 1A), in *MELK and POU5F1* (*OCT4*) (Panel A of figures 3 and 4).
50
51 205 Interestingly, such significant decrement was never observed during maturation of prepubertal gametes.
52
53 206 Comparison between adult and prepubertal oocytes showed a significant lower abundance for seven transcripts
54
55 207 (*ACTB, RPL19, DPPA3, ZAR1, MELK, NANOG, POU5F1*) in the young-derived GVs (Panel B of figures 1-5;
56
57 208 Table 3). This supports the hypothesis of a cytoplasmic immaturity of oocytes derived from young donors that
58
59
60

For Peer Review

1
2
3 209 may not be able to provide the proper amount of proteins needed for further development, as previously
4
5 210 suggested (Leoni et al, 2007).
6
7 211 Analysis of adult-derived 2 cell embryos showed a second major decrease for all transcripts around
8
9 212 fertilization, after which most mRNAs maintain a steady level and virtually disappear around the 8-16 cell
10
11 213 stage (Panel A of figures 1-5). At this point of development, all maternal transcripts are replaced by mRNAs
12
13 214 of embryonic origin. A significant decrease in transcript abundance was observed also in prepubertal derived 2
14
15 215 cell-embryos, but to a lesser extent, and the decrease during further development to 16C stage is more gradual
16
17 216 (Panel A of figures 1-5). As a consequence, comparison between adult- and young-derived embryos
18
19 217 consistently showed higher abundance of several mRNAs in prepubertal embryos at the 2C (11 out of 17
20
21 218 genes) and 4C stage (8 out of 17 genes; Table 3, panel B of figures 1-5), while no difference was observed at
22
23 219 8C and 16C. So less competent oocytes interestingly showed lower transcript abundance at the GV stage, but
24
25 220 generated embryos with higher mRNA levels just prior to genome activation. Such reversed trend indicates an
26
27 221 incomplete accumulation of mRNAs in the prepubertal oocyte, as earlier described, and a previously
28
29 222 unreported persistence of maternal transcripts in embryos approaching EGA, which indicates a delay in
30
31 223 degradation.
32
33 224 In all animals, the clearance of thousands mRNAs loaded into the egg by the mother is a key event in the
34
35 225 transition from maternal control of development to control by the embryonic genome (Giraldez et al, 2006;
36
37 226 Bushati et al, 2008; Bartel, 2009; Lund et al, 2009; Walzer and Lipshitz 2011); such elimination is indeed the
38
39 227 first event of Maternal to- Zygotic Transition (MZT), which is followed by the beginning of embryonic
40
41 228 genome transcription (Tadros and Lipshitz, 2009; Yartseva and Giraldez, 2015). Therefore, our observations
42
43 229 of abnormal transcript persistence in prepubertal embryos before EGA indicates some kind of impairment in
44
45 230 the mechanisms involved in MZT. Accordingly, embryos derived from young donors show lower
46
47 231 development to blastocyst stage (Table 2); most probably, the ones that stop around EGA fail to achieve the
48
49 232 dramatic cellular transitions that characterize MZT, including maternal transcript degradation.
50
51 233 Studies in Drosophila showed that some pathways of maternal mRNA clearance are inherited in the oocyte
52
53 234 cytoplasm, while others are synthesized de novo by the embryo, highlighting a combined action of both the
54
55 235 maternal cytoplasm and zygotic nucleus to the MZT (Bashirullah et al, 1999). The presence of two main
56
57 236 modes of mRNA degradation, maternal and zygotic, was confirmed in mouse embryos, where a subset of
58

59
60
For Peer Review

1
2
3 237 maternal transcripts is degraded soon after fertilization, while others show later decreases around EGA at the
4
5 238 two-cell stage (Hamatani et al, 2004). Two waves of transcript destabilization were observed also in human
6
7 239 embryos (Dobson et al, 2004; Zhang et al, 2009). As maternal and zygotic degradation activities appear to be a
8
9 240 general feature of the metazoan MZT, the existence of similar mechanisms in sheep may be hypothesized. In
10
11 241 this species EGA occurs around the 8 cell stage, so we may postulate that the first waves of transcript
12
13 242 degradation observed around oocyte maturation and fertilization are controlled by products of maternal origin,
14
15 243 while the final phases of transcript clearance that occur as EGA approaches depend on the proper activation of
16
17 244 the embryonic genome. This hypothesis would ascribe the higher mRNA abundance observed in 2C and 4C
18
19 245 prepubertal embryos to impairment of the first degradation activity, which depends on molecules of maternal
20
21 246 origin. Accordingly, prepubertal oocytes at the GV stage show lower transcript abundance, which may impair
22
23 247 its developmental competence. Oocytes with a proper transcriptome will in fact have better chances to achieve
24
25 248 fertilization, early embryo development and MZT (including maternal transcript clearance) and to complete
26
27 249 preimplantation and further development (Table 2). Conversely, oocytes carrying an inadequate transcriptome
28
29 250 may have impaired pathways of maternal mRNA clearance that prevent proper EGA and further development.
30
31 251 In the present work, the analysis of gene expression was performed on pools of ten oocytes/embryos, so the
32
33 252 observed patterns describe the mean abundance of potentially very different individual mRNA levels. It is
34
35 253 likely that each prepubertal pool comprises single oocytes/embryos with transcript levels similar to the adults
36
37 254 (prepubertal oocytes/embryos with better quality that will proceed with development) together with ones with
38
39 255 altered abundance (prepubertal oocytes/embryos with lower quality that are more likely to arrest at some point
40
41 256 of preimplantation development). Therefore, we propose that embryos with significant delay in transcript
42
43 257 degradation are likely to arrest during *in vitro* development, because they fail to proceed to MZT and EGA.
44
45 258 The observation of similar transcript level at 8-cell stage suggests that such arrest may occur at 2- and 4- cell
46
47 259 stage, so that only embryos with higher competence (and proper transcript degradation) would proceed to the
48
49 260 8- cell stage. Accordingly, expression patterns at the 16 cell and blastocyst stage support the hypothesis that
50
51 261 embryos able to activate their genome do not show altered transcript abundance on the basis of oocyte donor
52
53 262 origin. The similar expression in adults and prepubertals of the only mRNA of embryonic origin, *NANOG,*
54
55 263 further sustains such theory (Figure 4A and B). In other words, while pools of oocytes and very early embryos
56
57 264 include competent and not competent elements (many of which will not proceed to EGA and reach the

60

265 blastocyst stage), the selection that occurs during *in vitro* development allows only more competent embryos
266 to proceed with development, especially as EGA approaches. Accordingly, embryos that do not reach the
267 blastocyst stage often stop around the time of EGA during *in vitro* culture (Memili and First, 1999).

268 Although it is accepted that maternal transcript degradation around EGA is critical for embryo development,
269 the exact functions of this important mechanism are not clear (Tadros and Lipshitz 2009). Removal of
270 maternal mRNAs might be necessary to avoid abnormal mRNA dosage in the embryo. The persistence of
271 maternal mRNAs after EGA would indeed result in altered transcript dosage, as observed in often lethal
272 chromosomal aneuploidies (Lindsley et al, 1972). Alternatively, elimination of specific maternal transcripts
273 per se could be essential for early development and be instructive or permissive (Tadros and Lipshitz 2009). In
274 the former case, the gradual decrease in maternal mRNA levels in early embryos exerts a specific function, for
275 instance modulating the action of the relative encoded protein. Conversely, permissive maternal transcript
276 elimination would allow patterned embryonic transcripts to exert their influence. For example, ubiquitously
277 distributed maternal mRNAs could be eliminated to achieve a a spatially and temporally patterned
278 transcription of their embryonic counterparts. Finally, clearance may be aimed to remove transcripts that are
279 crucial during oogenesis (e.g. to protect the oocyte) but which are no longer needed in the embryo (Zeng et al,
280 2004; Pan et al, 2005). These hypotheses are not mutually exclusive and most probably all underlie the
281 importance of transcript clearance in early embryos. Although further research is needed to clarify the specific
282 effects of impaired maternal mRNA degradation during MZT, the evidence achieved so far clearly indicates
283 detrimental effects for embryo further development.

284 The present work has some limitations. Firstly, the paucity of material did not allow the quantification of the
285 RNA used for gene expression analysis. This opens up to different interpretations of the over abundance of
286 specific transcripts, such as stabilization of single RNAs on a background of general RNA degradation.
287 Another concern is that the study addressed only mRNA expression, while relative proteins were not
288 examined. Transcript levels do not necessarily represent the exact protein abundance, as gene expression is
289 controlled at multiple levels. Therefore it is not clear whether the increased transcript levels in prepubertal
290 embryos result in altered protein abundance, or if only transcript clearance is affected**.** Further research is
291 needed to clarify such issues.

2
3 293 In conclusion, our work confirmed that oocytes derived from adult or prepubertal donors have different *in*
4
5 294 *vitro* developmental capabilities and kinetics. We showed a cytoplasmic insufficiency of prepubertal GV
6
7 295 oocytes in terms of transcript abundance and for the first time a consistent delay in maternal transcript
8
9 296 degradation in prepubertal early embryos. We propose that the molecular shortage in the oocyte may affect its
10
11 297 developmental potential and impair the early pathways of maternal mRNA clearance in the embryo. We
12
13 298 suggest that such abnormal maternal transcript persistence may hinder further development and contribute
14
15 299 with a novel perspective to the complexity of developmental competence.

Materials and Methods

All chemicals were purchased from Sigma Chemical CO. (St. Louis, MO, USA) unless otherwise stated**.**

Oocyte Recovery and *In Vitro* Maturation

Oocytes were recovered from the ovaries of pre-pubertal (30– 40 days of age, body weight 6–10 kg) and adult (4–5 years of age, body weight 35–40 kg) Sarda sheep, collected at a local slaughterhouse and transported to the laboratory within 1 h in Dulbecco's phosphate-buffered saline (PBS) with antibiotics. After washing in fresh medium, ovaries were sliced using a micro-blade and the follicle content was released in TCM-199 medium (with Earle's salts bicarbonate) supplemented with 25 mmol HEPES, 0.1 g/L penicillin, 0.1 g/L streptomycin and 0.1% (w/v) polyvinyl alcohol.

Cumulus oocyte complexes (COCs) derived from both prepubertal and adult donors, showing several intact cumulus cell layers and a compact cytoplasm, were selected and matured *in vitro* (IVM) in TCM 199 supplemented with 10% heat treated oestrus sheep serum (OSS), 0.1 IU/ml FSH and 0.1 IU/ml LH (Pergonal, Serono Italy) and 100 µM cysteamine.

Then, 30–35 COCs were cultured for 24 h in 5% CO_2 in air at 38.5°C in four-well Petri dishes (Nunclon; Nalge Nunc, Roskilde, 100 Denmark) with 600 µL maturation medium, layered with 300 µL mineral oil. After IVM, oocytes underwent cumulus and corona cells removal by gentle pipetting and only oocytes presenting compact cytoplasm and the first polar body were selected.

***In vitro* fertilization and embryo development**

Frozen-thawed spermatozoa of one single ram of proven fertility (Sarda breed, 4 years old, body weight 55 kg) were used for all *in vitro* embryo production experiments. Two straws were thawed per IVF and spermatozoa were selected by swim-up technique (1×10^6 spermatozoa * mL). IVM oocytes were incubated in synthetic oviductal fluid (SOF) medium (Tervit et al*,* 1972) with 2% OSS, 1 µg/mL heparin and 1 µg/ mL hypotaurine for 22 h at 38.5°C in an atmosphere of 5% CO2 and 5% O_2 in N_2 in four-well Petri dishes (Nunclon, Nalge Nunc). Thereafter, presumptive zygotes were transferred and cultured for 8 days in four-well Petri dishes containing SOF plus essential and non-essential amino acids at oviductal concentrations (Walker et al, 1996)

+0.4% bovine serum albumin (BSA) under mineral oil, in a maximum humidified atmosphere with 5% CO_2, 5% O_2 and 90% N_2 at 38.5°C (Bogliolo et al. 2011).

At 24 and 30 hr post-fertilization the number of cleaved oocytes, showing two distinct blastomeres, was recorded.

The cleaved oocytes were transferred to a culture medium composed of SOF medium supplemented with 4 mg/ml BSA and essential and non essential amino acids at oviductal concentration (Walker et al, 1996) and kept in maximum humidified atmosphere at 38.5°C, 5% O_2, and 5% CO_2 up to the blastocyst stage.

Gene expression analysis

Details on gene expression analysis by real-time PCR are described according to the MIQE guidelines (Bustin et al, 2009).

Oocyte and embryo collection for gene expression analysis

The RNA samples were isolated from oocytes and embryos obtained during several IVM, IVF and IVC sessions, as follows:

- pools of denuded germinal vesicles (GV) and IVM metaphase II (MII) oocytes derived from prepubertal (P) or adult (A) donors (n=5 pools of 10 oocytes per stage and experimental group).
- *in vitro* produced (IVP) embryos at two- (2C), four- (4C), eight- (8C), 16- (16C) cell stage derived from P or A donors (n=3 pools of 10 embryos per stage and experimental group)
- IVP blastocysts derived from P or A donors (n=3 pools of 7 blastocysts per experimental group)

Oocytes and embryos were denuded via gentle pipetting in order to completely remove any somatic cell and added to 30 µl RLT buffer (RNeasy Micro Kit, Qiagen, Hilden, Germany), snap frozen in liquid nitrogen and stored at – 80°C until RNA isolation.

RNA Isolation and reverse transcription

For Peer Review

1
2
3 354 Total RNA was isolated from the pools of oocytes or embryos with the RNeasy Micro Kit (Qiagen, Hilden,
4
5 355 Germany) following manufacturer's instructions. Five pg of luciferase mRNA (Promega) were added to each
6
7 356 group prior to RNA extraction to account for RNA loss during the isolation process.
8
9 357 During the procedure, RNA was treated with DNase I to exclude any potential genomic DNA contamination.
10
11 358 Isolated RNA was eluted in 15 µL RNase-free water and 13.5 µL immediately used for reverse transcription–
12
13 359 polymerase chain reaction (RT-PCR).
14
15 360 Reverse-transcription was performed in a final volume of 20 µL, consisting of 50 mM Tris-HCl (pH 8.3), 75
16
17 361 mM KCl, 3 mM $MgCl_2$, 5 mM DTT, 1 mM dNTPs, 2.5 µM random hexamer primers, 20 U RNase OUT and
18
19 362 100 U SuperScript III RT (all purchased at Invitrogen Corporation, Carlsbad, CA). The reaction tubes were
20
21 363 incubated at 25°C for 10 min, then at 42°C for 1 h and finally at 70°C for 15 min to inactivate the reaction.
22
23 364 One tube without RNA and one with RNA, but without reverse transcriptase, were analysed as negative
24
25 365 controls. To quantify the mRNA recovery rate, 5 pg of luciferase mRNA (not subjected to RNA isolation) was
26
27 366 subjected to cDNA synthesis as well and subsequently quantified by Real Time PCR.
28
29 367
30
31 368 **Real time-polymerase chain reaction**
32
33 369 Primers for all analysed genes were designed to be intron-spanning and are listed in Table 4.
34
35 370 Relative quantification of transcripts was performed by real-time polymerase chain reaction (RT-PCR) in a
36
37 371 7900HT Fast Real-Time PCR System (Applied Biosystems). The PCR was performed in a 15 µL reaction
38
39 372 volume containing 7.5 µL 2× SYBR Green PCR Master Mix (Applied Biosystems, Foster City, CA), 200 nM
40
41 373 of each primer and cDNA equivalent to 0.25 oocytes or embryos.
42
43 374 The PCR protocol consisted in two incubation steps (50°C for 5 min and 95°C for 2 min), followed by 40
44
45 375 cycles of amplification program [95°C for 15 seconds (s) and gene-specific annealing temperature (see Table
46
47 376 4) for 30 s], a melting curve programme (65–95°C, starting fluorescence acquisition at 65°C and taking
48
49 377 measurements at 10-s intervals until the temperature reached 95°C) and finally a cooling step to 4°C.
50
51 378 Fluorescence data were acquired during the annealing step.
52
53 379 To minimise handling variation, all samples to be compared were run on the same plate using a PCR master
54
55 380 mix containing all reaction components apart from the sample.
56
57

For Peer Review

The PCR products were analysed by generating a melting curve to check the specificity and identity of the amplification product. For each primer pair, the efficiency of the PCR reaction was determined by building a standard curve with serial dilutions of a known amount of template, covering at least 3 orders of magnitude, so that the calibration curve's linear interval included the interval above and below the abundance of the targets. Only primers achieving an efficiency of reaction between 90 and 110 % (3.6 > slope > 3.1) and a coefficient of determination $r^2 > 0.99$ were used for the analysis.

The sizes of the RT-PCR products were further confirmed by gel electrophoresis on a 2% agarose gel stained with Sybr Safe (Invitrogen) and visualised by exposure to blue light. The PCR products were sequenced (Model 3130 xl Genetic Analyzer; Applied Biosystems, Foster City, CA, USA) after purification with MinElute PCR purification kit (Qiagen) and sequence identities were confirmed with BLAST (http://www.ncbi.nlm.nih.gov/BLAST/).

The relative quantification of the transcripts was performed after normalization against the exogenous *luciferase* mRNA levels and the number of oocytes and embryos (Su et al, 2007; Ohsugi et al, 2008; Evsikov and Evsikova 2009). Real-time RT-PCR data are presented as ΔCq, mean ± SEM. The relative amount of the target mRNA of each specific sample was obtained after subtraction of the calibrator expression level (ΔCq sample = Cq sample – Cq calibrator), where the calibrator was the sample showing the highest abundance (in most cases a pool of oocytes at the GV stage).

Statistical analysis

Gene expression data were analysed using the MINITAB Release 12.1 software package (Minitab Inc., State College, PA, USA). After testing for normality and equal variance using the Kolmogorov–Smirnov and Levene's tests respectively, transcript data were analysed with general linear model analysis of variance (ANOVA), followed by Tukey's *post hoc* comparisons when *P* values were significant.

Differences in maturation, fertilization, cleavage and blastocyst rates between prepubertal and adult oocytes were determined by the Chi-square test.

Differences were considered significant when $P < 0.05$.

	Oocytes	Matured	Cleaved (in hours post-fertilization)		
			24 hr	30 hr	Total
Prepubertal	740	697 (94.2%)	160 (38.1%) [a]	261 (61.9%) [a]	421 (60.4%) [a]
Adult	671	642 (95.7%)	341 (76.2%) [b]	106 (23.7%) [b]	447 (69.6%) [b]

Table 1. IVM and cleavage rates of prepubertal and adult oocytes.
Maturation rate is calculated on the initial number of oocytes. Total cleavage rates are calculated on the number of mature oocytes. Cleavage rates at 24 and 30 hr are calculated on total cleaved embryos. Different letters within each column indicate a significant difference ($P<0.05$). Hr: hours post-fertilization.

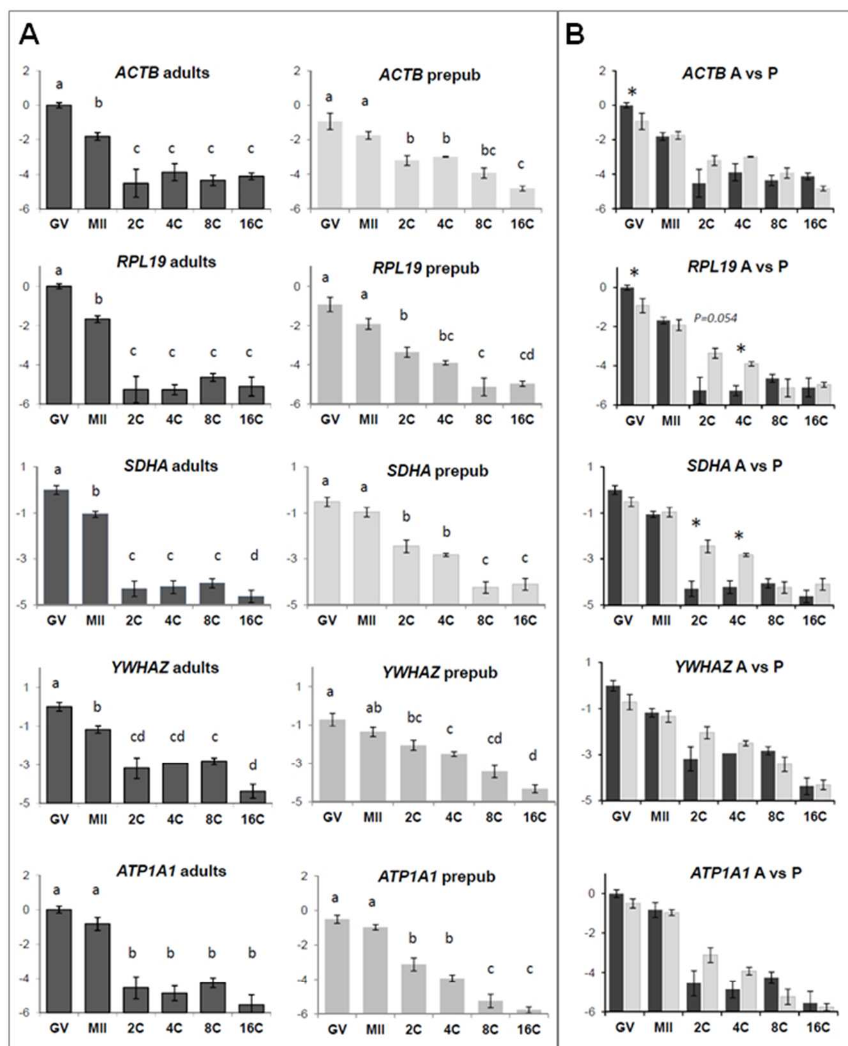

Figure 1. Relative expression of the housekeeping genes ACTB, RPL19, SDHA, YWHAZ and ATP1A1 in ovine immature (GV) and IVM MII oocytes (MII), in IVMFC two- (2C), four- (4C), eight- (8C), and 16-cell (16C) embryos derived from adults (A) or prepubertal (P) donors. Relative abundance values are expressed as ΔCq and show the mean value ± s.e.m. of five (GV and MII) and three (2C, 4C, 8C and 16C) replicates for each stage (each replicate= pool of 10 oocytes/embryos).

A. Different letters indicate a significant difference in relative mRNA abundance ($P < 0.05$) among the developmental stages.

B. * indicates a significant difference in relative mRNA abundance ($P < 0.05$) in pairwise comparisons of oocytes/embryos at the same developmental stage derived from adult or prepubertal donors (A vs P).
