10 Abstract

Ricotta fresca is a whey cheese susceptible of secondary contamination, mainly from *Pseudomonas* spp. The extension of the shelf life of refrigerated *ricotta fresca* could be obtained using protective cultures inhibiting the growth of this spoilage microorganism. A commercial biopreservative, Lyofast CNBAL, comprising Carnobacterium spp was tested against Pseudomonas spp. The surface of ricotta fresca samples were inoculated either with Pseudomonas spp or Pseudomonas and Carnobacterium spp. Samples were MAP packed, stored at 4°C and analyzed the day of the inoculum and 7, 14 and 21 days after the contamination. Microbiological analyses included total bacterial count, mesophilic lactic acid bacteria, Enterobacteriaceae, Pseudomonas spp, Listeria monocytogenes, moulds and yeasts. Pseudomonas mean initial contamination level was comparable in blank and artificially inoculated samples, respectively with values of 2.15±0.21 and 2.34±0.26 log cfu g⁻¹. Carnobacterium spp. significantly reduced the growth of Pseudomonas spp respectively of 1.28 log and 0.83 log after 14 and 21 days of refrigerated storage. Intrinsic properties and physico-chemical composition were also investigated. Limited variation of pH was observed in samples inoculated with the protective cultures, indicating low acidification properties of

Carnobacterium spp. Instead, no significant differences were observed for a_W, moisture, fat and proteins during storage and between inoculated and control samples.

Keywords: Carnobacterium spp.; protective cultures; Pseudomonas spp; ricotta; MAP.

1. Introduction

According to the Codex Standard for whey cheeses, these are solid, semi-solid, or soft products, which are principally obtained through either the concentration of whey or the coagulation of whey by heat with or without the addition of acid (Codex Alimentarius Codex Standard 284-1971). Whey cheeses are manufactured all over the world at artisanal and industrial level using different protocols depending on the country of origin. Ricotta, originally from Italy is the most renowned whey cheese in the world (Pintado & Malcata, 2000). However, in European countries, especially in the Mediterranean basin, wide varieties of whey cheeses are manufactured, mainly from ovine whey. These whey cheeses fall under several designation, e.g. Anthotyros (Greece), Anari (Cyprus), Requesón (Spain), Requeijao (Portugal), Broccio (France), Urdă (Balkans region). Ricotta fresca is a traditional whey cheese, which in Sardinia is produced by heat coagulation of sheep's milk whey remaining after the production of *Pecorino* type cheeses. The discontinuous manufacturing method include whey heating into open kettles to 80-82 °C. At this temperature the flocculated proteins rise and float on the surface. The curd is then scooped and transferred into perforated plastic baskets. Ricotta baskets are allowed to drain and to cool into a cold room. The detailed manufacturing process of Ricotta fresca has been previously described (Pala et al., 2016). Ricotta fresca is packed either in food wrapping paper or in polypropylene trays that are heat sealed with plastic lidding 107 46 film. Depending on the food business operator, atmospheric air or modified atmosphere packaging (MAP) is used. MAP conditions largely vary from one operator to another; with 30% CO₂ and 70% N₂ being the most used gas mixture used. The shelf life is designated under the responsibility of the

food business operator and varies from 5-7 days for wrapped Ricotta up to 21 days for MAP Ricotta. *Ricotta fresca* is poor in natural microflora since it is drastically reduced by the high temperature applied during the thermal denaturation of whey proteins (Pintado, Macedo & Malcata, 2001). Ricotta fresca is exposed to post-process contamination originating from the cheese-making environment, particularly in the steps between molding and packaging (Greenwood, Roberts & 130 54 Burden, 1991; Ibba et al., 2013). Given the high moisture (70-80%), elevated pH (6.10-6.80) and 132 55 the water activity (0.974-0.991) and the refrigerated storage (De Santis, Mazzette, Scintu, Deriu, & Carta, 1999), *Ricotta fresca* is an excellent substrate for the possible growth of several psychotropic pathogenic and spoilage microorganisms (De Santis & Mazzette, 2002). Common contaminants of Ricotta fresca include Pseudomonas spp., Enterobacteriaceae, Listeria monocytogenes, B. cereus and Arcobacter spp., yeast and moulds (Pintado, Macedo & Malcata, 2001; De Santis and Mazzette, 2002; De Santis et al. 2008; Ibba et al., 2013; Scarano et al.; 2014; Spanu et al., 2016; Tirloni et al., 2017). However, *Pseudomonas* spp. benefits of the selective advantage of the combination of low 147 62 temperature and long storage to overgrow other microorganisms, reducing the risk of pathogens 149 63 growth (Buchanan & Bagi, 1999; Carrascosa et al., 2015). Therefore, Pseudomonas spp. represents the main obstacle to extend Ricotta fresca shelf life (Pala et al., 2016). Growth of Pseudomonas spp. to level as high as 7 \log_{10} cfu g⁻¹ negatively affect the sensory properties of the product (Leriche et al., 2004). Important discoloration of the product derives by the secretion of yellow-green pyoverdin (Meyer et al., 2002) and of a blue pigment (Cantoni, Stella, Cozzi, Iacumin, & Comi, 2003; Martin, Murphy, Ralyea, Wiedmann & Boor, 2011; Andreani et al., 2015) from some *Pseudomonas* spp. In order to reduce the initial microbial load at production, it is essential the strict 164 70 application of good hygiene and good manufacturing procedures. A previous investigation, 166 71 conducted on Sardinian cheese-making plant manufacturing *Ricotta fresca*, showed that there is an 170 73 association between secondary contamination with Pseudomonas spp. and the level of implementation of the food safety management system at plant level (Pala et al., 2016). There is the

need of additional strategies to control the growth of Pseudomonas spp., especially in industrial MAP Ricotta fresca. The use of bio preservatives to extend the shelf life of whey cheeses has been previously tested (Davies, Bevis, & Delves-Broughton, 1997; Samelis, Kakouri, Rogga, Savvaidis, & Kontominas, 2003; Martins, Cerqueira, Souza, do Carmo Avides, & Vicente et al., 2010). Carnobacteria are Gram positive rod shaped lactic acid bacteria (LAB) isolated from different echological niches. The genus *Carnobacterium*, is able to produce bacteriocins therefore, it has been used as protective cultures to provide durability and safety to various types of foods (Elsser-Gravesen & Elsser-Gravesen, 2013). Of the species included in the genus Carnobacterium, only two, C. divergens and C. maltaromaticum, are frequently isolated from natural environment and dairy products (Leisner, Laursen, Prevost, Drider, & Dalgaard, 2007; Afzal et al., 2010). Carnobacterium spp, due to similar growth conditions (pH and temperature variation) of psychrotrophic spoilage and pathogen microorganisms, can improve the durability of chilled foods by reducing or inhibiting the growth of *Pseudomonas* spp. To date, little investigation has been conducted to validate the efficacy of bio preservatives against Pseudomonas spp. in sheep Ricotta fresca cheese. A commercial protective culture, consisting of a selected strain of Carnobacterium spp producing bacteriocins, the Lyofast CNBAL (Clerici-Sacco Group, Como, Italy) was sprayed on Ricotta fresca surface (Spanu et al., 2017). The study demonstrated a good adaptation to the substrate with growth during refrigerated storage with no acidification of the product. Carnobacterium spp. showed a competitive activity against *Pseudomonas* spp. in *Ricotta fresca*. However, the experiment was conducted on naturally contaminated samples. The main objective of the present study was to evaluate, as a possible innovation in the manufacturing process of *Ricotta fresca*, the use of a protective culture to control the superficial contamination against spoilage 225 96 microorganisms. With this aim, the efficacy of Carnobacterium spp against the growth of ²²⁹ 98 Pseudomonas spp was tested in artificially contaminated Ricotta fresca.

2. Materials and methods

1 2.1. Samples

The study was conducted on 162 *Ricotta fresca* samples provided by a local industrial cheesemaking plant using the whey remaining after the production of hard sheep's milk cheese (e.g. *Pecorino* type cheeses). The samples were truncated cone shaped cheese with an upper base ca.7.5 cm wide and a lower base ca. 5 cm wide, weighing approximately 1.1 kg. Fifty-five *Ricotta fresca* samples were randomly selected from each of three different batches (each batch was manufactured in a different day of production). Samples were packed in MAP (gas mixture was 30% CO₂ and 70% N₂) using rigid polypropylene trays sealed with high-barrier peelable laminated films. Films were made of bioriented polyamide and cast polypropylene with O₂ T.R. (20°- 65% R.H.) of ~30 cc/m², 24 h. After packaging samples were transported refrigerated to the laboratory within 24 from the production. Within each batch, samples were randomly allocated to the following treatment: artificial inoculation with *Pseudomonas fluorescens* (RfPf), artificial inoculation with *Pseudomonas fluorescens* and *Carnobacterium* spp (RfPf+C), no treatment (RfB). Part of the samples (Ph-Ch) were used for the determination of intrinsic properties (pH and a_w), percentage composition (moisture, fat, protein) and headspace gas composition (CO₂ and O₂).

³116 2.2 Artificial inoculation

The RfPf units (n. 36) were the units artificially inoculated with *Pseudomonas fluorescens*, which served as positive control samples. The preparation of the inoculum was conducted according to the guidelines prepared by NACMCF (2010). A mixture of five *Pseudomonas fluorescens* wild type strains was used to challenge *Ricotta fresca* units. The strains were recovered from naturally contaminated *Ricotta fresca* during a previous investigation (Pala et al., 2016). In order to avoid overrepresentation of clones, isolates were submitted to genetic characterization using pulsed-field gel electrophoresis (PFGE). Only strains with different restriction profile were included in the preparation of the inoculum. All the strains were stored at -80 °C in Brain Heart Infusion (BHI)

²⁹⁸ 299 125 broth (Oxoid, Basingstoke, UK) with glycerol (20% v/v). In order to account for natural 300 301¹²⁶ contamination levels and allow the enumeration of the inoculum, the target level was 10^2 cfu g⁻¹ of 302 ₃₀₃ 127 product surface (Spanu et al., 2014). Preliminary trials were conducted in order to determine the 304 growth condition necessary to standardize the level of inoculum and to adapt strains to refrigeration 305 128 306 temperature. Each strains was subcultured by streaking onto the non selective trypticase soy agar 307 129 308 medium (TSA, Biolife, Milan, Italy) and incubated for 24 h at 25 °C. A single colony was picked 309 130 310 ³¹¹ 131 and transferred into tubes containing the non-selective brain heart infusion broth, BHI (Oxoid, 312 ³¹³132 Basingstoke, UK). Tubes were incubated overnight at 25°C in a shaking water bath to obtain cells 314 ³¹⁵ 316 **133** in the same physiological state (late exponential or early stationary phase). Adaptation of the strains 317 318 **13**4 to refrigeration was conducted by subculturing in BHI broth at 4±2 °C until cells were in the 319 ₃₂₀ 135 exponential growth phase (Uyttendaele et al., 2004). Equal volumes of each individual culture were 321 mixed in a sterile flask. From the mixture were prepared adequate serial decimal dilution in ₃₂₂ 136 323 phosphate buffered saline (Biolife) to adjust the concentration to 10⁴ cfu mL⁻¹. After the removal of 324137 325 the sealing film, an aliquot of 1.5-2.0 mL of inoculum was evenly sprayed on the surface of Ricotta 326138 327 328 139 fresca (ca. 290 cm², corresponding to ca. 40-50 g of product). All concentrations were confirmed 329 ³³⁰140 by plate count on TSA (Biolife). 331

³³²141 After the inoculum of Pseudomonas fluorescens, the RfP+C units (n. 36) were also inoculated with 333 ³³⁴ 335 **142** the protective cultures Lyofast CNBAL (Clerici-Sacco Group, Como, Italy) consisting of a selected 336 ₃₃₇143 strain of *Carnobacterium* spp producing bacteriocins with an optimum growth temperature between 338 25-45 °C. The commercial formulation is a freeze-dried powder, which, according to ₃₃₉ 144 340 manufacturer's instructions, was diluted in Phosphate-buffered saline (PBS) solution (Oxoid) to 341 145 342 obtain 10⁶ cfu g⁻¹ of product. With this aim, the suspension was adjusted to a concentration of 10⁸ 343146 344 cfu mL⁻¹ and 1.5-2.0 mL were evenly spraved on the *Ricotta fresca* surface. *Carnobacterium* spp 345147 346 ³⁴⁷ 148 concentrations were confirmed by count on agar plates. After the inoculation, all samples (included 348 ³⁴⁹ 149 untreated blank samples) were repacked in MAP (30% CO2 and 70% N2) using the FP Basic Sec 350

351

359

³⁵⁷ 358 **150** tray sealer (Ilpra, Vigevano, Italy). Blank samples were packed under the same conditions of the other samples with no further manipulation. All samples were stored under refrigeration $(+ 4^{\circ}C)$ until analysis were performed.

2.3 Experimental design

Triplicate samples of each of the three batches of Ricotta fresca were analyzed the day of 366 154 inoculation (T_0), and after different days of refrigerated storage, respectively 7 (T_7), 14 (T_{14}) and 21 368 155 ³⁷⁰156 (T_{21}) . At each time-point RfPf, RfPf+C and RfB samples were analyzed for the determination of the ³⁷²157 microbiological profile. In order to mimic the evolution of the microbiological profile under the 373 ³⁷⁴ 375 158 foreseeable condition during retail selling, a subset of RfPf+C samples were opened seven days 376 377 **159** after the inoculation and analyzed after three further days of storage (T_{10}) at $8\pm2^{\circ}C$ (abuse 378 ₃₇₉160 temperature). Ricotta fresca samples were also analyzed for the determination of the intrinsic 380 properties, composition and headspace gas analysis. The detailed design including sample units, ₃₈₁ 161 382 testing times and related analysis is described in table 1. 383162

2.3. Microbiological profile 385 163

³⁸⁷ 164 Ricotta fresca samples submitted to microbiological examination were prepared according to ISO 388 ³⁸⁹ 165 6887-1:1999. Briefly, the initial suspension and decimal dilution was conducted after the sterile 390 ³⁹¹ 166 collection of to 25 g of ricotta surface into a sterile plastic stomacher bag. 225 mL of Buffered 392 ³⁹³ 394 **167** Peptone Water were added and the sample homogenized using a stomacher. Decimal serial dilutions 395 ₃₉₆168 were obtained by transferring 1 mL of the initial suspension into a tube containing 9 mL of sterile 397 diluent. If required, these operations were repeated using the 10⁻² to obtain further serial decimal ₃₉₈ 169 399 dilution. The pour-plating procedure was used for the enumeration of aerobic mesophilic bacteria, 400 170 401 mesophilic lactic acid bacteria and Enterobacteriaceae, yeasts and moulds. Plate Count Agar and 402 171 403 MRS medium at pH 5.7 (Biolife, Milan, Italy) were incubated at $30^{\circ}C \pm 1^{\circ}C$ for 72 h \pm 3 h 404 172 405 ⁴⁰⁶ 173 respectively for the enumeration of aerobic mesophilic bacteria (ISO 4833:2003) and mesophilic 407 408 174 lactic acid bacteria (ISO 15214: 1998). The enumeration of Enterobacteriaceae was conducted 409

- 410
- 411
- 412

416 417 175 using the plate count technique without resuscitation, incubating Violet Red Bile Agar plates 418 419¹⁷⁶ (Biolife) at 35-37°C for 24 h (ISO 21528-1:2004). Enumeration of yeast and molds was conducted 420 421 **177** using Chloramphenicol Yeast Glucose Agar plates (Biolife) incubated at $25 \pm 1^{\circ}$ C up to 5 days 422 (ISO 6611/IDF094:2004). For the enumeration of Pseudomonas spp (ISO/TS 11059:2009), 0.1 mL ₄₂₃178 424 of each decimal dilution were spread over the surface of Pseudomonas Agar Plates added with PP 425 **179** 426 supplement (Biolife) and incubated at 25 °C \pm 1°C for 48 h \pm 2 h. For the detection of *Listeria* 427 180 428 ⁴²⁹181 monocytogenes (ISO 2004a) the initial suspension was supplemented with Fraser Half Selective 430 ⁴³¹ 182 Supplement (Biolife) and incubated at 30 °C for 24 h (primary enrichment). After incubation 0.1 432 433 434 **183** mL of the primary enrichment were subcultured into 10 mL of Fraser Broth and incubated at 37°C 435 436 **18**4 for 24-48 h (enrichment). From both, pre-enrichment and enrichment broth, 0.1 mL were streaked 437 ₄₃₈ 185 onto Agar Listeria Ottaviani Agosti (ALOA, Biolife) and Oxford (Oxoid, Basingstoke, UK) agar 439 plates and incubated at 37 °C for up to 48 ±3 h. Enumeration of L. monocytogenes (ISO 2004b) 440 186 441 was a conducted streaking 1 mL volume of the initial dilution onto both three ALOA and three 442187 443 Oxford agar plates and incubated at 37 °C for up to 48 ±3 h. The enumeration of Carnobacterium 444 188 445 446 189 spp was conducted using MRS modified by increasing the pH to 8.5, omitting acetate, and 447 ⁴⁴⁸190 substituting glucose for sucrose (Hammes et al., 1992). 449

450 451 **191** *2.5. Pseudomonas fluorescens characterization*

452 453 **192** A total of five colonies from each sample containing typical colonies on Pseudomonas Agar Plates 454 ₄₅₅ 193 were confirmed with two different PCR protocols, one used to identify Pseudomonas fluorescens 456 (Scarpellini et al., 2004) and the other to identify Pseudomonas spp and Pseudomonas aeruginosa 457 **19**4 458 (De Vos et al., 1997). Among the confirmed Pseudomonas fluorescens strains, up to three isolates 459 195 460 per samples were randomly selected and analyzed using pulsed-field gel electrophoresis (PFGE). 461 196 462 463 197 After DNA extraction, agarose plugs were digested with enzyme restriction SpeI (Roche 464 ⁴⁶⁵ 198 Diagnostics,

466 467

- 468
- 469
- 470 471
- 472

Laval, Quebec, Canada) (Maslow, 1993). PFGE was performed using the protocol described by (Gershman et al., 2008). The obtained restriction profiles were analyzed by visual examination to distinguish inoculated strains among each other and from strains originating by natural contamination.

484 203 2.5. Intrinsic properties, composition and headspace gas analysis

Determination of pH and a_w was conducted using pH meter GLP22 (Crison Instruments SA, 486 204 487 ⁴⁸⁸205 Barcelona, Spain) and water activity meter Aqualab 4TE (Decagon, Pullman, WA, USA), 489 ⁴⁹⁰206 respectively. The near-infrared spectrophotometer system for the determination of centesimal 491 492 493**207** composition (%) of fat, moisture, protein and total solids was used. Ricotta fresca samples were 494 495**208** accurately mixed, placed into Petri dishes and read in the light spectrum of 850-1050 nm using the 496 497²⁰⁹ compositional FoodScanTM device (FOSS, Analytic, Hillerød, Denmark). The headspace gas 498 composition was conducted on MAP ricotta fresca samples on the sealed packages before 499210 500 performing other analysis. Measure of combined residual O2 % and CO2 % were obtained piercing 501211 502 the lid using a sterile needle connected to the Dansensor gas analyser (PBI Dansensor, Ringsted, 503212 504 ⁵⁰⁵213 Denmark). To avoid gas leaks during the penetration of needle, 15 Ø mm septum (PBI Dansensor), 506 ⁵⁰⁷214 were applied on the film lid before measurements of headspace gas composition. 508

⁵⁰⁹₅₁₀**215** *2.6. Statistical analysis*

511 512**216** Differences among average microbiological group counts (log₁₀ cfu g⁻¹), headspace gas 513 ₅₁₄217 concentration (%), intrinsic properties and centesimal composition (%) over time (T₀, T₇, T₁₄ and 515 T_{21}) and among types of samples (RfB, RfPf and RfPf+C) within one time point were compared ₅₁₆218 517 using Fisher's least significant difference test. Statistical analyses were performed with Statgraphics 518219 519 Centurion XVI software (Stat Point Technologies, Warrenton, VA, USA). The effectiveness of 520 **220** 521 522 221 Carnobacterium spp in controlling the growth of *Pseudomonas fluorescens* was evaluated 523 ⁵²⁴222 computing the minimum difference (Δ) between of the log₁₀ cfu g⁻¹ between RfPf and RfPf+C 525 ⁵²⁶223 samples at each time point $(T_7, T_{14} \text{ and } T_{21})$. 527

3. Results

3.1. Microbiological profile

In *Ricotta fresca* blank samples the total bacterial count was $3.12\pm0.71 \log_{10}$ cfu g⁻¹ at T₀ and gradually increased during refrigerated storage up to $6.34\pm0.87 \log_{10}$ cfu g⁻¹ at T₂₁. The mesophilic lactic acid bacteria ranged between $2.25\pm0.06 \log_{10}$ cfu g⁻¹ at T₀ and $3.83\pm1.06 \log_{10}$ cfu g⁻¹ at T₂₁. Enterobacteriaceae were observed in one samples both at T₀ and at T₇ with counts of ca. 2 log₁₀ cfu g⁻¹; their concentration increased to $3.48\pm0.58 \log_{10}$ cfu g⁻¹ at T₂₁. Pseudomonas aeruginosa was never detected both in inoculated and blank samples. Natural contamination with Pseudomonas spp was observed in two samples out of nine with a mean count of $2.15\pm0.21 \log_{10}$ cfu g⁻¹ at T₀ and increased to $6.48\pm0.78 \log_{10}$ cfu g⁻¹ at T₂₁. In *ricotta fresca* samples inoculated with the protective culture, *Carnobacterium* spp. grew from the initial concentration of $6.36 \pm 0.32 \log_{10}$ cfu g⁻¹ at T₀ to $8.78 \pm 0.25 \log_{10}$ cfu g⁻¹ at T₂₁. The comparison between *ricotta fresca* samples inoculated with Pseudomonas spp plus the protective culture and samples inoculated only with Pseudomonas spp showed similar level of initial contamination, ca. 2.30 log₁₀ cfu g⁻¹. After 14 and 21 days of refrigerated storage Pseudomonas concentration was respectively 1.28 and 0.83 log₁₀ cfu g⁻¹ lower in ricotta fresca inoculated with *Carnobacterium* spp protective culture (P < 0.05). Yeast and molds were occasionally reported, with maximum values below 4 \log_{10} at T₂₁. The complete microbiological profile with mean counts (log₁₀ cfu g⁻¹; $\bar{x} \pm$ SD) over time is reported in table 2. L. monocytogenes was never detected on either blank samples and ricotta inoculated with biopreservatives. Microbiological analysis conducted on RfPf+Copen samples analyzed at T₁₀ showed the following counts (within brackets positive samples over tested samples): total bacterial count $8.40 \pm 0.63 \log_{10} \text{cfu g}^{-1}$ (n = 9/9), mesophilic lactic acid bacteria $3.12 \pm 0.41 \log_{10} \text{cfu g}^{-1}$ (n = 6/9), Carnobacterium spp 6.90 \pm 1.89 log₁₀ cfu g⁻¹ (n = 9/9), Enterobacteriaceae 2.15 log₁₀ cfu g⁻¹ (n = 1/9), *Pseudomonas* spp 7.65 ± 0.51 log₁₀ cfu g⁻¹ (n = 9/9), yeast and molds 2.86 ± 0.43 log₁₀ cfu g⁻¹ (n = 5/9), while *L. monocytogenes* was never detected.

- 590

9 3.2. Physico-chemical characteristics and MAP gas composition

A moderate decrease of pH was observed over time in all *ricotta fresca* samples. However, significant difference between blank samples and in samples inoculated with *Carnobacterium spp* were observed only at T₂₁, showing respectively values of 6.60 ± 0.04 and 6.48 ± 0.07 (P<0.05). The a_w was stable over time and between sample types ranging from 0.984 ± 0.001 and 0.987 ± 0.001 . No significant difference was observed among blank samples and ricotta inoculated with biopreservatives in moisture, fat and protein composition, showing respectively a mean content of 72.38±3.15, 15.67±3.99 and 10.70±0.93. The O₂ content in the headspace increased from the initial level of $0.52\pm0.24\%$ up to $1.30\pm1.28\%$ at T₇, to decrease again as low as 0.03 ± 0.05 at T₂₁. Instead, the CO₂ content decreased from T₀ to T₂₁ respectively from $16.71\pm0.61\%$ to 7.16%. No significant difference in gas composition were observed between blank and inoculated *ricotta fresca* samples. Intrinsic properties, composition and gas composition in the headspace ($\bar{x}\pm$ SD) during the refrigerated storage are reported in table 3.

262 3.3. Pseudomonas spp natural and artificial contamination

From RfPf+C a total of 108 were confirmed as *Pseudomonas fluorescens* strains and typable by **PFGE**. The comparison of the restriction profiles obtained showed that 103 strains (95.4%) belonged to one of the five *Pseudomonas fluorescens* strains of the mix used for the artificial contamination. Five strains (4.6%), showing a different restriction profile, were from natural contamination.

5 6269 **4. Discussion**

Ricotta fresca cheese is particularly susceptible of secondary contamination from the processing Ricotta fresca cheese is particularly susceptible of secondary contamination from the processing

environment and represents an excellent substrate for the growth of psychotropic pathogenic and
spoilage microorganisms (De Santis and Mazzette, 2002; De Santis *et al.* 2008; Ibba *et al.*, 2013;
Scarano *et al.*; 2014; Spanu *et al.*, 2016). Therefore, it is necessary to provide *ricotta fresca* with a

651 ⁶⁵² 653**274** protection against the growth of unwanted bacteria. A possible strategy is the use of microbiological 655²⁷⁵ 654 cultures aimed to control the multiplication of contaminants. Previous investigation has been 656 ₆₅₇276 conducted to assess the feasibility of using different biopreservatives in ricotta fresca (Spanu et al., 658 2017). The study, conducted on naturally contaminated ricotta, indicated *Carnobacterium* spp as a 659277 660 possible protective culture to be used to control the growth of *Pseudomonas* spp. The present study 661 278 662 was aimed to validate the efficacy of *Carnobacterium* spp inoculated on the surface of ricotta fresca 663279 664 665280 before packaging to control the growth of *Pseudomonas* spp in artificially contaminated samples. 666 ⁶⁶⁷281 The microbiological profile of controls (not inoculated) samples showed a natural intitial 668 669 670**282** contamination level of *Pseudomonas* spp of ca. 2 log cfu g⁻¹. *Pseudomonas* spp grew to level as 672²⁸³ 671 high as 7 log cfu g⁻¹ after 21 days of refrigerated storage. *Carnobacterium* spp showed a good 673 ₆₇₄284 adaptation to the substrate showing an increase in mean counts of ca. 2 log cfu g⁻¹ during 675 refrigerated storage. The use of Carnobacterium spp was effective in reducing Pseudomonas spp ₆₇₆285 677 concentration respectively of 1.28 log cfu g⁻¹ and 0.83 log cfu g⁻¹ after 14 and 21 days of storage. 678286 679 These results are in agreement with previous studies conducted on naturally contaminated sheep 680287 681 682₂₈₈ ricotta fresca (Spanu et al., 2017). This is explained by the level of artificial contamination used in 683 ⁶⁸⁴289 the present study, which was comparable with the natural level of Pseudomonas contamination. In 685 ⁶⁸⁶290 turn, this finding highlight the need of considering ricotta fresca as a "high risk" production and of 687 ⁶⁸⁸ 689</sub>291 improving the procedures based on the HACCP principles put in place in Sardinian cheesemaking 690 ₆₉₁ 292 plants. Despite the growth of *Carnobacterium* spp, little difference was observed in pH value 692 ₆₉₃293 between ricotta fresca inoculated with the protective culture and control samples. Variation of pH 694 over time was comparable with previous observations (Pala et al., 2016; Spanu et al., 2017). No 695294 696 significant differences were observed in a_w and composition between blank samples and samples 697 **29**5 698 699296 inoculated with Carnobacterium spp. However, the possible impact on sensory properties of the 700 ⁷⁰¹ 297 protective culture should be further investigated. In the present study sensory analysis were not 702 703 298 performed because the level of *Pseudomonas* spp contamination at T₁₄ was already as high as 6 704 705 12

650

log₁₀, compatible with possible alteration of the product. Before performing sensory analysis it is necessary first to guarantee the safety of the product and the absence of any alteration that could compromise acceptability of consumers.

The evolution of the gas composition in the headspace followed a trend which was expected. After MAP packaging a residual concentration of ca. 0,52% O₂ persist in the headspace, which increases during the first week of storage to above 1.0% and successively decrease until ca. 0.03% at T₂₁. This could be explained with the release into the headspace of O₂ incorporated in the food matrix at first, than the successive reduction is attributable to the consumption of O₂ during the successive growth of the microorganisms. The differences in the CO₂ content in the headspace with respect to the concentration used in the gas mixture was the result of prompt gas solving in the product, while the successive CO₂ reduction could be related to permeability of the plastic lidding film. To mimic foreseeable condition during retail selling after 7 days of refrigerated storage Ricotta fresca samples were opened by removal of the film lid and exposing the product to atmospheric air. Samples were then submitted to three days of thermal abuse (T_{10}) at 8 ± 2 °C. Abused samples showed a significant increase in aerobic mesophilic bacteria count and of Pseudomonas spp that reached respectively, level as high as 8 log cfu g⁻¹ and 7.65 log cfu g⁻¹. This further confirms the importance of the cold chain in preserving the microbiological durability of *ricotta fresca*.

5. Conclusion

The use of Carnobacterium spp as a protective culture, sprayed on the surface of ricotta fresca during refrigerated storage, demonstrated to be effective to obtain a reduction of ca 1 log of Pseudomonas spp growth. Despite Carnobacterium spp does not serve a single step against *Pseudomonas*, it may be part of an integrated approach where several combined control measures limit the growth of the microorganism to an acceptable level.

Table 1. Experimental design: number of *Ricotta fresca* samples and types of analysis performed at each sampling time.

| | | | Samp | ling tim | e | | |
|--|------------------------|----------------|----------------|-----------------|-----------------|-----------------|-------|
| Analysis | type of samples | T ₀ | T ₇ | T ₁₀ | T ₁₄ | T ₂₁ | Total |
| - Microbiological profile: aerobic mesophilic bacteria; mesophilic lactic | RfB | 9 | 9 | - | 9 | 9 | 36 |
| acid bacteria; <i>Enterobacteriacae; Pseudomonas</i> spp; L. | RfPf | 9 | 9 | - | 9 | 9 | 36 |
| monocytogenes; Carnobacterium spp; yeast and molds. | RfPf+C | 9 | 9 | - | 9 | 9 | 36 |
| 11.75 | RfPf+C _{open} | - | - | 9 | - | - | 9 |
| Intrinsic properties: pH and a_w; composition (%): moisture; fat; protein; | Ph-Ch | 9 | 9 | 9 | 9 | 9 | 45 |
| - Headspace composition (%): CO ₂ ; O ₂ | | | | | | | |
| Total | | 36 | 36 | 18 | 36 | 36 | 162 |

 $\overline{T_0}$ = day of inoculum; T_7 , T_{10} , T_{14} , and T_{21} = respectively 7, 10, 14 and 21 days of storage after the inoculum. RfB: not inoculated blank samples; RfPf: samples inoculated with *Pseudomonas fluorescens*; RfPf+C: samples inoculated with both *Pseudomonas fluorescens* and *Carnobacterium* spp; RfPf+C_{open}: samples inoculated with both *Pseudomonas fluorescens* and *Carnobacterium* spp and stored refrigerated after the removal of the film lid; Ph-Ch: samples used for the determination of intrinsic properties, composition and headspace gas.

| Microbiol group | Type of samples | Day of storage | | | | | |
|---------------------------------|-----------------|---|---------------------------------------|--------------------------------------|--------------------------------------|--|--|
| Microbial group | | T ₀ | T ₇ | T ₁₄ | T ₂₁ | | |

Table 2. Evolution of the microbiological profile (log₁₀ cfu g⁻¹; $\bar{x} \pm SD$) of ricotta during refrigerated storage by sample type.

 $\overline{T_0}$ = day of inoculum; $\overline{T_7}$, $\overline{T_{10}}$, $\overline{T_{14}}$, and $\overline{T_{21}}$ = respectively 7, 10, 14 and 21 days of storage after the inoculum. RfB: not inoculated blank samples; RfPf: samples inoculated with *Pseudomonas fluorescens*; RfPf+C: samples inoculated with both *Pseudomonas fluorescens* and *Carnobacterium* spp;

Means in the same row with different superscript letter were significantly different (P<0.05); means in the same column among type of samples with different superscript number were significantly different (P<0.05). Values within brackets indicate the prevalence of positive samples.
